

LEGENDARY TRADERS · MARKET WIZARDS: THE NEXT GENERATION · CHAPTER 4

# Lukas Fröhlich

*An audited 1,132,045% year, then three strategies that are almost opposites*

**1,132,045%**

2020 return, independent  
agreed-upon procedure

**309.3%**

Average annual compound rate,  
Jan 2020 to Dec 2025

**35.5%**

Maximum drawdown over the same  
six years

The record and what it cannot tell you, the small-cap dilution short, the pyramiding rule, the named trades, the 2022 drawdown, the counterweight, and a printable pre-trade check. Every figure is from the chapter unless labelled as our own arithmetic.

# 1 • The record, and what it cannot tell you

| Figure                 | What the chapter states                                     | What it measures                                             |
|------------------------|-------------------------------------------------------------|--------------------------------------------------------------|
| <b>892,000%</b>        | The 2020 return he claimed publicly                         | His own figure. The independent review found it understated. |
| <b>1,132,045%</b>      | 2020 return per the independent firm, Modified Dietz method | Performance, adjusted for deposits and withdrawals           |
| <b>37,127%</b>         | Ending 2020 balance against beginning balance               | Account growth, depressed by withdrawals during the year     |
| <b>Factor of seven</b> | Growth in his account since 2020                            | Account growth; basis not specified in the text              |
| <b>309.3% a year</b>   | Average annual compound rate, Jan 2020 to Dec 2025          | Six-year compound performance                                |
| <b>35.5%</b>           | Maximum drawdown, same six years                            | Peak-to-trough decline                                       |

## How the authors checked it

Statements, tax documents and existing Big Four audit reports reviewed; brokers contacted; then an independent agreed-upon procedure commissioned from a top auditing firm, because the documents were complex and the authors lacked forensic accounting expertise. The procedure found his public figure was too low.

## Our arithmetic, not the book's

37,127% growth = ending balance about 372 times the start. 1,132,045% time-weighted = money multiplying about 11,300 times. The gap, a factor of about 30, is the compounding that withdrawn profits did not get to do. 309.3% a year for six years multiplies money about 4,700 times, less than 2020 alone on a time-weighted basis. Sevenfold growth over 2021 to 2025 would be about 48% a year. The multi-year figures do not reconcile on one basis from the text; the book's calculation endnote would settle it.

### Net worth: the honest answer

The chapter gives percentages only, no dollar figures for his account. No net worth can be estimated from it. His stated goal is to grow the account to \$1 billion, a motivating target rather than a fixed aim.

## 2 · Career arc and the rules that ended the blow-ups

| When                   | What happened                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Early childhood</b> | France; parents had met in Germany and moved for his father's job                                               |
| <b>Just before 10</b>  | Family moves back to Germany after the financial crisis; French school, then German school without the language |
| <b>Age 13</b>          | Starts trading about \$500 of gift money in an account in his father's name; currencies, then CFDs at 50–100:1  |
| <b>School years</b>    | Four or five blown accounts, about \$500 to \$1,000 each; a DAX short loses 200% and he sells his bicycle       |
| <b>Late school</b>     | Free videos up to 10 hours a day; Tim Grittani; research with Miah Lee until 2 or 3am                           |
| <b>2018</b>            | Finishes school; broker with borrow via a Bahamian entity; several thousand dollars from his 18th birthday      |
| <b>2020</b>            | Small-cap shorts plus mid-cap breakouts; audited 1,132,045% year                                                |
| <b>Mid-2021</b>        | Stops mid-cap breakouts as the bull market stalls                                                               |
| <b>2022</b>            | Moves to contrarian long-term investing; drawdown of around 40%                                                 |
| <b>2024–2025</b>       | Alibaba and Centene theses; 200-day average as the gate                                                         |

### The four beginner mistakes (Schwager's list)

No defined trading method. No risk control. Excessive leverage. No post-trade reviews. Fröhlich adds his own: stubbornness about taking losses, which took longest to fix.

#### The two rules that stopped the wipeouts

A maximum potential loss on any single stock, and a maximum loss across the portfolio on any single day. Coyle calls this the most critical takeaway of the interview: the rules did not make him profitable, they kept him alive long enough to become profitable.

### 3 · Strategy one: the small-cap dilution short

A company with \$1m of working capital burning \$500,000 a quarter must raise money within six months. In small caps, raises tend to coincide with sharp gap-ups: a handful of small-cap underwriters buy stock, warrants or convertibles cheaply, a press release appears (sometimes recycled, sometimes, he says, fabricated), the stock rallies pre-market on thin volume, gaps up, and they sell into it. Many gapped 100%+ and closed down 30%.

| Layer              | What he did                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Fundamental</b> | SEC filings for impending working-capital problems; judged whether news was bogus; researched underwriters and their deal patterns; skipped shorts where prospects had improved |
| <b>Technical</b>   | Separated gaps by size (50% vs 300%) and intraday path; aggregated ~250 similar cases into an average-day template; research back to 2000                                       |
| <b>Entry</b>       | Waited for weakness, such as the first red candle                                                                                                                               |
| <b>Size</b>        | About half the intended position first; added only if working; average trade ~10% of equity in those years                                                                      |
| <b>Attempts</b>    | Three failed shorts in one stock in one day, then stop; may retry the next day                                                                                                  |
| <b>Exit</b>        | Usually by the close: best exit per research, expensive borrow on small floats, overnight gap risk                                                                              |

#### Four stop types

| Stop                      | How it works                                                                                     |
|---------------------------|--------------------------------------------------------------------------------------------------|
| <b>New daily high</b>     | Exit if the stock makes a new high for the day                                                   |
| <b>Percentage</b>         | Exit a set percentage above entry                                                                |
| <b>Standard deviation</b> | Exit on a set number of standard deviations above the open (his preferred; adapts to volatility) |
| <b>Time</b>               | Exit if the expected daily pattern has not appeared by a given time                              |

SONN, 14 April 2020: scanner hit on a huge gap on massive volume; historical analogues favoured a fall; cash running out; warrants and convertibles likely to be converted and sold. About 20 minutes of analysis. First short stopped for a small loss, second near the high covered near the opening range, third after a bounce.

## 4 · Strategy two: mid-cap breakouts and the pyramiding rule

| Element              | Criterion                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Universe</b>      | Market cap \$1bn–\$5bn, smaller floats; 2020 themes hyped on social media                                    |
| <b>Catalyst</b>      | Any positive news, validated by a 40%–100% move and a volume surge                                           |
| <b>Consolidation</b> | Ideally holds the upper half of the range before breaking out                                                |
| <b>Entry</b>         | Breakout, or earlier in the upper range: cup-and-handle, or converging above the 20-day EMA                  |
| <b>Initial size</b>  | About two-thirds of the intended position                                                                    |
| <b>Stops</b>         | Below consolidation / below breakout-day low / trailing 20-day EMA / 9-day EMA if parabolic                  |
| <b>Exits</b>         | Hysteria (distance from 9 and 20 EMA, consecutive up days, volume, rising ADTR), wide excursions, resistance |
| <b>Environment</b>   | Strong bull markets only. Traded spring 2020 to mid-2021, then stopped                                       |

### The independent-setup rule

Add only when a second setup appears that would qualify as an initial entry with no position on. Size the add so a stop-out cancels the open profit exactly. If the add fails quickly, the whole trade is dead.

Our worked example: 1,000 shares from \$20, stock at \$30, new stop \$27

| Scenario                | Original 1,000 | Added 2,330 | Net             |
|-------------------------|----------------|-------------|-----------------|
| <b>Stop hit at \$27</b> | +\$7,000       | –\$6,990    | About breakeven |
| <b>Runs to \$40</b>     | +\$20,000      | +\$23,300   | +\$43,300       |
| <b>Runs to \$60</b>     | +\$40,000      | +\$69,900   | +\$109,900      |

*Illustration by Complete Trader's Edge. Ignores slippage, gaps through the stop, costs and tax.*

GRWG, late 2020 to early 2021: August 2020 earnings sparked a 100%+ week; months of consolidation into the 9 and 20 EMA; initial entry there; add on the second earnings catalyst; add on a pullback to the 20 EMA; exit on hysteria.

## 5 · Strategy three, sizing, and the 2022 drawdown

| Golden goose part         | Meaning                                                                               |
|---------------------------|---------------------------------------------------------------------------------------|
| <b>Neglected or hated</b> | Strong company discounted for risks he judges external or overblown                   |
| <b>Fundamentals</b>       | Viable long-term model, exposure to growth themes                                     |
| <b>Valuation</b>          | A genuine discount; high short interest is a plus                                     |
| <b>Chart</b>              | Consolidating; substantial size only above the 200-day average or on a major breakout |
| <b>Catalyst</b>           | Expected or realised, not priced by the market (the surprise)                         |
| <b>Portfolio fit</b>      | Ideally uncorrelated with existing holdings                                           |

Alibaba: 2024 P/E near 10, low double-digit earnings growth, cloud optionality, big buybacks; stimulus expected. Six failed probes from 2022 cost over 2% of equity; then scaled in and pyramided, making more than 20 times the losses. Profits taken into parabolic 2025 rallies; re-entered on 200-day reclaims and tests. Centene (summer 2025): bet that ACA subsidies would be protected; the chapter gives no outcome.

### Sizing and Kelly

Around 5% of the account per theme, up to about 10%. He thinks successful traders under-size relative to half-Kelly, but keeps to about 5% for peace of mind. Kelly:  $F = Pw - (Pl \div W)$ , where W is average win divided by average loss. Over-betting hurts more than under-betting; double Kelly erases all compound growth.

2022 mistake: bought falling stocks because they were cheap, too large, and added to losers; drawdown around 40% (the audited six-year maximum is 35.5%; the chapter does not reconcile them). Lessons: never trade your whole net worth, wait for a bottom and the 200-day, watch the market cycle, plan for the worst case.

## 6 · Counterweight and a pre-trade check

| Caution                         | Why it matters                                                                                          |
|---------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>No dollar base</b>           | Percentages only; extreme returns are easier on small capital                                           |
| <b>2020 was a moment</b>        | Uncrowded small caps and a stimulus euphoria; setups fell from 2–3 a day to 2–3 a week                  |
| <b>Survivor's path</b>          | Four or five blow-ups at 100:1 were survivable because the stakes were small and his parents housed him |
| <b>Do not copy the switches</b> | Coyle: most traders who change style for a money goal end badly                                         |
| <b>Online statistics</b>        | Win rates and expectancy figures circulating about him are not in the chapter                           |

### Seven questions before any trade

- ☐ 1. What is my maximum loss on this position, and on the whole account today?
- ☐ 2. How many times have I already tried this idea today? Three is the cap.
- ☐ 3. Who is forced to buy or sell here, and why?
- ☐ 4. Is this an initial entry, or an addition? If an addition, would I take it with no position on?
- ☐ 5. If the stop is hit, does the addition cost more than my open profit?
- ☐ 6. Does the current market suit this strategy, or am I trading last year's environment?
- ☐ 7. Am I sizing below my own estimate of the optimum?
